(54) Title: APPLICATION PROGRAM INTERFACES IN AN OPERATING SYSTEM

(57) Abstract

A set of Application Program Interfaces (APIs) for a resource-limited environment are disclosed. The APIs provide a mechanism for a computer application to interface with various components and modules of an operating system for a resource-limited environment. The APIs further provide a mechanism to interface with input/output devices commonly found in embedded systems running in a resource-limited environment.

APPLICATION PROGRAM INTERFACES IN AN OPERATING SYSTEM

5

FIELD OF THE INVENTION

This invention relates generally to computer operating systems, and more particularly to application program interfaces for resource limited operating systems.

RELATED FILES

10

This application claims the benefit of U.S. Provisional Application No. 60/078946, filed March 23, 1998, which is hereby incorporated herein by reference.

BACKGROUND OF THE INVENTION

The rapid evolution of personal computer technology continues to produce personal computers (PCs) that are smaller, cheaper and faster than their predecessors. Where computers once occupied entire rooms, they are now small
25 enough to fit in the palm of a user's hand, hence the name "Palm-size PCs". In addition, PCs are now small enough to be placed in environments outside of the home or office, such as an automobile. Further more, the new PCs may be embedded in a variety of consumer devices and specialized industrial controllers. For the purposes of this application, all of the above-referenced PCs will be
30 referred to collectively as "embedded systems."

The reduced size of embedded systems means that certain sacrifices need to be made. For example, a typical embedded system does not have fixed or removable disk drives such as hard disk, floppy disk, CD-ROM or DVD-ROM drives, with the persistent storage of a typical embedded system comprising flash
5 memory or volatile memory with a battery refresh. In addition, the amount of RAM in the typical embedded system is also limited.

In addition, output resources typical to a desktop PC may be missing or severely limited in an embedded system. For example, the display for a typical embedded system may comprise a small LCD screen with limited resolution and
10 capable of displaying only grayscale or a limited number of colors. In certain environments, such as the automobile, the display may be an LCD screen with a limited number of fixed icons and text areas. The display may be augmented with a computerized speech facility.

Similarly, input resources may be limited or adapted for use in embedded
15 systems. For example, many embedded systems do not have a mouse or other pointing device. In addition, some hand-held devices do not have a physical keyboard. Such embedded devices may use a touch sensitive display in conjunction with a virtual keyboard placed on the display. In addition, embedded devices may employ speech recognition for input.

20 As a result of the above, specialized operating systems capable of running in the resource-limited environment of the embedded system have been developed. An example of such an operating system is the Windows CE™ operating system from Microsoft Corporation.

Applications running on the embedded system must also be capable of
25 running in the resource limited environment described above. In embedded systems comprising Palm-size PCs, these applications are typically specialized versions of applications available on the bigger siblings of the Palm-size PC, such as calendar programs, personal information managers, calculators, dictionaries and the like.

In other environments, the applications running on the embedded system may be more specialized. For example, in an AutoPC, the applications may comprise applications that interface with an audio system, applications that report and use position and navigation information, and applications that monitor
5 the condition and state of various other systems present in the automobile.

In order to accommodate a large number of different application needs, operating systems typically provide APIs (Application Programming Interfaces) to a wide variety of functionality that is common to many differing applications. Any one application generally uses only a small subset of the available APIs.
10 Providing a wide variety of APIs frees application developers from having to write code that would have to be potentially duplicated in each application. However, in the resource limited environment of the embedded system, there is typically a much more limited set of APIs available. This is because there is generally insufficient persistent and non-persistent memory available to support
15 a large number of different APIs. Thus, a developer writing an application for an embedded system may find that he or she must develop code that would ordinarily be provided by the operating system in a desktop's or other larger computer's operating system.

As a result of the above, there is a need in the art for an operating system
20 capable of running in the resource limited environment of an embedded system. Such an operating system should be customizable and adaptable to the wide variety environments that system designers may choose to place embedded systems, allowing developers to include only those components and modules that are necessary for a particular environment. In addition, the operating system
25 should include APIs to operating system provided components in order prevent applications designers from having to duplicate commonly needed code. Finally, the operating system should provide APIs for components and modules that meet the unique input and output needs of an embedded system.

SUMMARY OF THE INVENTION

The above-mentioned shortcomings, disadvantages and problems are addressed by the present invention, which will be understood by reading and studying the following specification.

5 A system is presented that includes a set of Application Program Interfaces (APIs) for a number of software modules and components for resource limited environments. One example of a resource limited environment is the embedded system, which comprises a variety of consumer devices and specialized industrial controllers, along with hand-held, or palm-size personal
10 computers.

One aspect of the system is that the combination of components and modules included in an operating system for resource limited environments is customizable and flexible. This allows an embedded system designer to include only those components and modules that are necessary for a particular
15 environment. As a result, scarce memory is not consumed by unneeded components, allowing more memory to be devoted to applications and other modules and components that are needed in the embedded system.

Another aspect of the system is that APIs are provided that meet the unique input and output needs of the typical embedded system. For example,
20 many embedded systems do not provided a keyboard or mouse for input. The system provides APIs to components and modules that provide alternative mechanisms of providing input. These alternative mechanisms include APIs to handwriting recognition engines that "read" strokes on a touch sensitive screen, and APIs to voice input components that allow a user to issue spoken commands
25 to the system. Further, the system provides APIs to components that output audible speech for those environments where a display monitor is impractical.

Another aspect of the system is that the handling of "out of memory" conditions is customizable by an embedded system designer. This is important to systems with limited resources, because out of memory conditions are more likely to occur.

5 A further aspect of the system is that an API to a position and navigation component is provided. This is useful for embedded system environments that are mobile, such as automobiles, trucks, and boats.

The APIs summarized above, and various other APIs, will be described in detail in the sections that follow.

10 The present invention describes systems, clients, servers, methods, and computer-readable media of varying scope. In addition to the aspects and advantages of the present invention described in this summary, further aspects and advantages of the invention will become apparent by reference to the drawings and by reading the detailed description that follows.

15 **BRIEF DESCRIPTION OF THE DRAWINGS**

FIG. 1 shows a diagram of the hardware and operating environment in conjunction with which embodiments of the invention may be practiced;

FIG. 2 is a diagram illustrating a system-level overview of exemplary embodiments of an operating system for a resource limited environment; and

20 FIG. 3 is a diagram further illustrating the relationship of modules, components and APIs according to an embodiment of the invention.

DETAILED DESCRIPTION OF THE INVENTION

In the following detailed description of exemplary embodiments of the invention, reference is made to the accompanying drawings that form a part
25 hereof, and in which is shown by way of illustration specific exemplary embodiments in which the invention may be practiced. These embodiments are described in sufficient detail to enable those skilled in the art to practice the invention, and it is to be understood that other embodiments may be utilized and that logical, mechanical, electrical and other changes may be made without

departing from the spirit or scope of the present invention. The following detailed description is, therefore, not to be taken in a limiting sense, and the scope of the present invention is defined only by the appended claims.

The detailed description is divided into four sections. In the first section,
5 the hardware and the operating environment in conjunction with which
embodiments of the invention may be practiced are described. In the second
section, a system level overview of the invention is presented. In the third
section, various APIs are presented allowing applications to interface with
various modules and components of an operating system. Finally, in the fourth
10 section, a conclusion of the detailed description is provided.

Hardware and Operating Environment

FIG. 1 is a diagram of the hardware and operating environment in
conjunction with which embodiments of the invention may be practiced. The
description of FIG. 1 is intended to provide a brief, general description of
15 suitable computer hardware and a suitable computing environment in
conjunction with which the invention may be implemented. Although not
required, the invention is described in the general context of computer-
executable instructions, such as program modules, being executed by a
computer, such as a personal computer, a hand-held or palm-size computer, or an
20 embedded system such as a computer in a consumer device or specialized
industrial controller. Generally, program modules include routines, programs,
objects, components, data structures, etc., that perform particular tasks or
implement particular abstract data types.

Moreover, those skilled in the art will appreciate that the invention may
25 be practiced with other computer system configurations, including hand-held
devices, multiprocessor systems, microprocessor-based or programmable
consumer electronics, network PCS, minicomputers, mainframe computers, and
the like. The invention may also be practiced in distributed computing

environments where tasks are performed by remote processing devices that are linked through a communications network. In a distributed computing environment, program modules may be located in both local and remote memory storage devices.

- 5 The exemplary hardware and operating environment of FIG. 1 for implementing the invention includes a general purpose computing device in the form of a computer 20, including a processing unit 21, a system memory 22, and a system bus 23 that operatively couples various system components including the system memory to the processing unit 21. There may be only one or there
- 10 may be more than one processing unit 21, such that the processor of computer 20 comprises a single central-processing unit (CPU), or a plurality of processing units, commonly referred to as a parallel processing environment. The computer 20 may be a conventional computer, a distributed computer, or any other type of computer; the invention is not so limited.
- 15 The system bus 23 may be any of several types of bus structures including a memory bus or memory controller, a peripheral bus, and a local bus using any of a variety of bus architectures. The system memory may also be referred to as simply the memory, and includes read only memory (ROM) 24 and random access memory (RAM) 25. A basic input/output system (BIOS) 26,
- 20 containing the basic routines that help to transfer information between elements within the computer 20, such as during start-up, is stored in ROM 24. In one embodiment of the invention, the computer 20 further includes a hard disk drive 27 for reading from and writing to a hard disk, not shown, a magnetic disk drive 28 for reading from or writing to a removable magnetic disk 29, and an optical
- 25 disk drive 30 for reading from or writing to a removable optical disk 31 such as a CD ROM or other optical media. In alternative embodiments of the invention, the functionality provided by the hard disk drive 27, magnetic disk 29 and optical disk drive 30 is emulated using volatile or non-volatile RAM in order to conserve power and reduce the size of the system. In these alternative

embodiments, the RAM may be fixed in the computer system, or it may be a removable RAM device, such as a Compact Flash memory card.

In an embodiment of the invention, the hard disk drive 27, magnetic disk drive 28, and optical disk drive 30 are connected to the system bus 23 by a hard disk drive interface 32, a magnetic disk drive interface 33, and an optical disk drive interface 34, respectively. The drives and their associated computer-readable media provide nonvolatile storage of computer-readable instructions, data structures, program modules and other data for the computer 20. It should be appreciated by those skilled in the art that any type of computer-readable media which can store data that is accessible by a computer, such as magnetic cassettes, flash memory cards, digital video disks, Bernoulli cartridges, random access memories (RAMs), read only memories (ROMs), and the like, may be used in the exemplary operating environment.

A number of program modules may be stored on the hard disk, magnetic disk 29, optical disk 31, ROM 24, or RAM 25, including an operating system 35, one or more application programs 36, other program modules 37, and program data 38. A user may enter commands and information into the personal computer 20 through input devices such as a keyboard 40 and pointing device 42. Other input devices (not shown) may include a microphone, joystick, game pad, satellite dish, scanner, touch sensitive pad, or the like. These and other input devices are often connected to the processing unit 21 through a serial port interface 46 that is coupled to the system bus, but may be connected by other interfaces, such as a parallel port, game port, or a universal serial bus (USB). In addition, input to the system may be provided by a microphone to receive audio input.

A monitor 47 or other type of display device is also connected to the system bus 23 via an interface, such as a video adapter 48. In one embodiment of the invention, the monitor comprises a Liquid Crystal Display (LCD). In

addition to the monitor, computers typically include other peripheral output devices (not shown), such as speakers and printers.

The computer 20 may operate in a networked environment using logical connections to one or more remote computers, such as a remote computer 49.

5 These logical connections are achieved by a communication device coupled to or a part of the computer 20; the invention is not limited to a particular type of communications device. The remote computer 49 may be another computer, a server, a router, a network PC, a client, a peer device or other common network node, and typically includes many or all of the elements described above relative
10 to the computer 20, although only a memory storage device 50 has been illustrated in FIG. 1. The logical connections depicted in FIG. 1 include a local-area network (LAN) 51 and a wide-area network (WAN) 52. Such networking environments are commonplace in offices, enterprise-wide computer networks, intranets and the Internet.

15 When used in a LAN-networking environment, the computer 20 is connected to the local network 51 through a network interface or adapter 53, which is one type of communications device. When used in a WAN-networking environment, the computer 20 typically includes a modem 54, a type of communications device, or any other type of communications device for
20 establishing communications over the wide area network 52, such as the Internet.

The modem 54, which may be internal or external, is connected to the system bus 23 via the serial port interface 46. In a networked environment, program modules depicted relative to the personal computer 20, or portions thereof, may be stored in the remote memory storage device. It is appreciated that the
25 network connections shown are exemplary and other means of and communications devices for establishing a communications link between the computers may be used.

The hardware and operating environment in conjunction with which embodiments of the invention may be practiced has been described. The

- computer in conjunction with which embodiments of the invention may be practiced may be a conventional computer an hand-held or palm-size computer, a computer in an embedded system, a distributed computer, or any other type of computer; the invention is not so limited. Such a computer typically includes
5. one or more processing units as its processor, and a computer-readable medium such as a memory. The computer may also include a communications device such as a network adapter or a modem, so that it is able to communicatively couple other computers.

System Level Overview

- 10 A system level overview of the operation of an exemplary embodiment of the invention is described by reference to FIGs. 2 and 3. The concepts of the invention are described as operating in a multiprocessing, multithreaded operating environment on a computer, such as computer 20 in FIG. 1. The exemplary operating environment comprises what is known in the art as an
- 15 operating system. In this environment one or more applications, such application 226, interface with various modules and components of the operating system. In addition, the various modules and components of the operating system interface with each other. Finally, the modules, components and applications interface with hardware 202 present on the computer through what
- 20 is known in the art as a device driver module, and through an Original Equipment Manufacturer (OEM) adaptation layer 208. In one embodiment of the invention, there are two types of device drivers, built-in drivers 206 and installable drivers 204. The various modules will now be described in further detail.
- 25 The core system interface 220 is the module through which applications can access the operating system. The core system interface 220 includes functions to transfer API calls to the appropriate operating system server process.
- In addition to including or exporting the APIs selected, the core system interface 220 includes components to support the following:

- Localization
- Local heap and memory allocation
- Serial port device driver thunks
- Telephony API (TAPI)

5 The shell module 222 manages the user interface and handles such tasks as launching software applications. In one embodiment of the invention, the operating system provides shell components that enable an embedded system designer to develop a customized shell 222 that satisfies the requirements of the target platform. Included in these components are:

- 10 • A Control Panel with applets familiar to desktop Windows users. The following applets are included: Communications; Display; Keyboard; Network; Owner; Password; Power; Regional Settings, Remove Programs; Pointing Device Settings (Stylus); Sounds and Volume.
- 15 • A Notification API that lets an application register its name and an event with the system. When the event occurs, the kernel will automatically start the named application. The API also allows an application to register a specific date and time at which the application should start.
- 20 • Common controls and common dialogs, which are designed to provide to the user clear, simple, and meaningful information and a means to furnish input to the system and applications as needed.
- 25 • A command line processor (that is, a console application) that supports a set of standard input and output API calls.
- 30 • Connectivity components (for example, to support remote application programming calls) between the development workstation and the embedded system target platform.

35 In conjunction with a desktop, the shell module 222 also includes a desktop and task manager component that can be optionally included or

replaced. The task manager component includes the following basic functionality:

- An Active Tasks list of all the currently running, top-level applications;
- 5 • A Run button that allows a user to launch a software application;
- A Switch To button that allows a user to switch to an application selected in the Active Tasks listbox.
- 10 • An End Task button that allows a user to terminate an application selected in the Active Tasks listbox.
- A Cancel button that allows a user to close the Task-Manager window.
- 15 • Monitors the level of main battery and backup battery power (for battery-operated target platforms) and displays an appropriate warning dialog box.
- 20 • Monitors system memory usage in the system and sends a message to all top-level windows when the available system memory drops below a specific threshold. This allows applications to respond to the message by reducing their memory usage as much as possible.

The Add-on Technologies module 224 allows an embedded system developer to optionally include components such as OLE/COM automation that supports development of ActiveX-based applications, an active desktop shell and an Internet browser. Other components that can be included are Visual Basic
25 run-time and Java script, and a subset of the Microsoft Foundation Classes (MFC). A further optional component that can be provided is a handwriting recognition engine with associated APIs. In one embodiment of the invention, handwriting applications interface with a touch sensitive input device through a component providing a software interface to the touch sensitive device.

The kernel module 214 represents the base operating system functionality that must be present on all platforms. The kernel module includes memory management, process management, exception handling, and support for
5 multitasking and multithreading.

In one embodiment of the invention, the kernel 214 is designed specifically for small, fast, embedded devices. In this embodiment, the kernel supports a single 4GB address space (a 2GB virtual address and a 2GB physical address range). In an embodiment of the invention, this 4GB address space is
10 divided into 33 "slots", each of which has a size of 32MB. The kernel protects each process by assigning each process to a unique, open slot in memory. The invention, however, is not limited to any particular physical or virtual address space or slot size, and other sized may be chosen as those of skill in the art will recognize.

15 The kernel 214 protects applications from accessing memory outside of their allocated slot by generating an exception. Applications can check for and handle such exceptions by using the try and except Windows CE functions. In one embodiment of the invention, the system is limited to 32 processes, but the number of threads running in a process is limited only by the amount of available
20 memory. Those of skill in the art will appreciate that other values for the maximum number of processes could be chosen.

The file system module 218 contains the functions that support persistent storage on the embedded system target platform. This storage is referred to as the "object store" and includes three different ways to store user data:

- 25
- The file system. The file system typically supports common file manipulation functions, such as functions to create files and directories, read and write to files, and retrieve file and directory information.

- The registry. The system registry is similar to the registries of the Windows 95 and Windows NT operating systems. The registry for all applications, including the applications bundled in ROM, is stored in the object store.
- 5 • The Database API. The operating system, in one embodiment of the invention, has its own structured storage to offer an alternative to exposing user and application data in files or the registry. For example, a database is useful for storing raw data that an application will process before displaying to the end-user. Hand-held PC
10 applications typically store schedule and contact information in databases.

In one embodiment of the invention, the file system managed by file system module 218 is a transactioned system to reduce the possibility that data will be lost due to a critical failure, such as loss of power. Additionally, in one
15 embodiment of the invention, the file system module 218 implements a scheme (transactioned) of "mirroring" to mirror or track file system operations (not transactioned). The purpose for this implementation is to be able to restore a file system volume in the case that power is lost during a critical sequence of operations being performed on the volume.

20 In one embodiment of the invention, the operating environment combines the Win32 User and GDI (Graphics Device Interface) libraries into a GWES (Graphics, Windowing, and Events Subsystem) module 212. The event manager and window manager are analogous to Win32 User, and the Win32 GDI is replaced with a smaller GDI more suitable to embedded systems. The GWES
25 module 212 includes multiplatform GDI components (supporting an associated display driver) that support color and grayscale display, palette management, TrueType fonts, Raster fonts, cursors, and printer device contexts (DCs).

The GWES module 212 also supports a window management component that provides API functions tailored for the smaller display sizes typical of
30 embedded operating systems.

The operating environment of various embodiments of the invention is event-driven. GWES module includes components to handle events, which in one embodiment of the invention are implemented as messages.

Communications module 216 includes a variety of communications
5 component options to support communications hardware. This includes serial, parallel, and network (wired and wireless) communications. Communications module 216 includes the following selectable communications features:

- Serial I/O support
- Networking support including:
 - 10 • NDIS 4.0 for local area networking
 - PPP and SLIP for serial link and modem networking
 - Client-side Remote Access Server (RAS)
 - Internet protocols
 - 15 • Telephony API (TAPI)
 - PC Card support
 - Infrared transceiver support

In one embodiment of the invention, an embedded systems designer must develop the OEM adaptation layer 208 to create the platform specific kernel
20 module 214. The OEM Adaptation Layer (OAL) module 208 allows an embedded system developer to adapt the operating system for a specific target platform by creating a thin layer of code that resides between the kernel module 214 and the target platform hardware 202. The OAL module 208 is specific for a particular CPU and target platform.

25 The OAL module 208 includes interfaces such as the following:

- Interrupt service routine (ISR) handlers to support device drivers
- Real-time clock (RTC)
- 30 • Interval timer (used for the scheduler operation)

In one embodiment of the invention, the RTC and interval timer does not need to be adapted because it is provided on the CPU. In this case, these interfaces are implemented in the kernel module 214 rather than in the OAL 208.

In addition to managing such functions as timing and power, the primary purpose of the OAL is to expose the target platform's hardware 202 to the kernel module 214. That is, each hardware interrupt request line (IRQ) is associated with one interrupt service routine (ISR). When interrupts are enabled and an
5 interrupt occurs, the kernel calls the registered ISR for that interrupt.

Built in drivers 206 are device drivers that are linked with GWES module 212 when building the operating system. Examples of such drivers are the notification LED driver or the battery driver. These drivers are called "built-in device drivers" because they ultimately form part of the same executable image
10 as the rest of the operating system. Built-in device drivers each have a custom interface to the rest of operating system.

Device Manager module 210 is a module that handles installable device drivers. In one embodiment of the invention, The Device Manager 210 performs the following tasks:

- 15 • Initiates the loading of a driver at system start up, or when it receives a notification that a third-party peripheral has been attached to the target platform. For example, when a PC Card is inserted, Device Manager 210 will attempt to locate and load a device driver for that PC Card.
- 20 • Registers special filesystem entries with the kernel that map the Stream I/O Interface functions used by applications to the implementation of those functions in an installable device driver.
- Finds the appropriate device driver by obtaining a Plug and Play ID or by invoking a detection routine to find a driver that can handle the
25 device.
- Loads and tracks drivers by reading and writing registry values.
- Unloads drivers when their devices are no longer needed. For example, Device Manager 210 will unload a PC Card device driver when the card is removed.

30 In one embodiment of the invention, Installable Device Drivers 204 exist as standalone DLLs (Dynamic Link Library) that are managed by the Device

Manager 210. Installable device drivers 204 support some types of native devices, any peripheral devices that can be connected to the target platform, and any special purpose devices that are added to the platform. This covers devices such as modems, printers, digital cameras, PC Cards (also known as PCMCIA cards), and others.

In one embodiment of the invention, installable device drivers 204 use a common interface by which their services are exposed to applications. This interface is the Stream I/O Interface.

A description of the relationships between components, modules and the APIs they expose to applications is presented with reference to FIG. 3. A module 308 is a major functional block of an operating environment such as operating system 200 of FIG. 2. Module 308 exposes an API 302 to applications such as application 226 of FIG. 2 that allows the application to interface and call methods or functions implemented by the module 308.

Modules may optionally include one or more components 306. Components 306 are groups of functions and data that provide capabilities on a smaller scale than modules 308. Like a module 308, a component 306 also exposes an API 304 that other applications, modules, and components may use to call methods or functions implemented by the component 306.

As can be seen from the discussion above, the various embodiments of the invention provide advantages over prior systems. One benefit is that the operating system is modular. This allows an embedded system designer to create an operating environment that is optimized for their unique hardware development platform and application. The developer can select varying combinations of the above-described modules and components for inclusion in the operating environment. For example, a developer can build an embedded operating system that contains the kernel and a selected set of communications but does not provide a graphical user interface. Thus, the invention is not limited to any particular combination of modules and components.
